35 **ABSTRACT.**

36 **Background.**

37 The remains of a 3-5 year-old child from the late medieval cemetery serving the Priory of St. Peter
38 and St. Paul, Taunton, Somerset, UK was the subject of an aDNA study.

39 **Objective.**

40 The aim was to distinguish between two differential diagnoses suggested by earlier osteological
41 examination of the remains; either tuberculosis or Langerhans cell histiocytosis.

42 **Findings.**

43 The remains tested positive for MTB complex markers, corroborating this diagnosis reached on
44 osteological grounds. Based on positivity for the *mtp40* element and a deletion in the *pks15/1*
45 locus, we conclude that infection was due to a strain of the human pathogen *M.tuberculosis*
46 belonging to lineage 4 . Although DNA recovered from the case was heavily fragmented, sex
47 determination by amelogenin PCR suggested these are the remains of a young male child. The
48 findings are discussed considering additions to the literature since the original report.

49 **Conclusions.**

50 Descriptions of tuberculosis in children from this period are rare and burial SK2077 represents the
51 first UK example of a pre-adolescent individual to have a molecular diagnosis combined with
52 osteological pathology. This provides an important reference of childhood tuberculosis and insight
53 into the likely presence of tuberculosis in the mediaeval adult population served by this cemetery.

58

59 **1.1 BACKGROUND.**

60 One of us (HD-H) has previously described the remains of a young child (AD 1150-1539) from the
61 late mediaeval cemetery associated with the Priory of St. Peter and St. Paul, Taunton, Somerset,
62 UK [1]. The priory was an Augustinian house of canons founded in the early 12th century by
63 William Giffard (or Gyffarde), Lord Chancellor of England (1093-1101) and Bishop of Winchester
64 (1100-1129 AD). The Priory was in use until the Dissolution in 1539 AD and much of it was
65 demolished by the mid 16th century [2]. Osteological analysis carried out on 190 inhumations
66 excavated during 2005 showed a mixed cemetery population, indicating it served a lay community
67 [3].

68
69 The remains under review in the present study, Sk2077, come from burials recovered from area 4
70 of the 2005 excavations, sited towards what appears to be the northern edge of the cemetery
71 (Figure 1).

72
73 The remains are those of a young child aged between 3-5 years at the time of death. A number of
74 skeletal indicators suggested a probable diagnosis of tuberculosis. These included a circular lytic
75 lesion on the right parietal bone at the posterior medial corner, close to where the sagittal and
76 lambdoidal sutures meet. The cranial lesion penetrates through both the inner and outer tables as
77 a circular hole 10mm in diameter. Ectocranially, the hole has a smooth edge and some porosity
78 surrounds the area. The endocranial surface has a larger circular area of bone destruction,
79 involving the diploic space, 16mm in diameter with a sharp edge. The occipital bone exhibits
80 resorptive endocranial lesions, also known as *serpens endocrania symmetrica* (SES) along the area
81 of the occipital sulcus, covering 45mm length and 12-15mm width. There are slight lytic lesions on
82 the atlas, on the superior edge of the posterior rim, and on the axis, on the inferior edge of the
83 lamina; destructive lytic lesions on the visceral surface of three rib fragments and a small area of
84 periostitis (woven bone) present on one rib and periosteal new bone formation (woven bone) on
85 both femora [1]. It has been shown that in documented cases of tuberculosis in juveniles,
86 periosteal reaction on long bones may not be uncommon [4]. An alternative diagnosis considered
87 at the time of the previous examination was eosinophilic granuloma, a variant of Langerhans cell
88 histiocytosis [5]. The main aim of the present study was to investigate and if possible confirm the
89 diagnosis of tuberculosis using an ancient DNA (aDNA) approach.

90
91

92 **2. METHODS.**

93 **2.1 Estimation of age.**

94 SK2077 was aged by dental eruption and formation [6]; radiographs of the sub-adult mandibles
95 from this collection were taken, where intact, to aid in the identification of tooth formation
96 stages; this was the case for SK2077.

97

98 **2.2 Samples collected.**

99 Bone samples were collected from three locations on the skeleton of individual Sk2077 for aDNA
100 analysis. These sites included fragments of two ribs, one with a lytic lesion and a section of the
101 posterior rim of the atlas with lesion. Initially, DNA extracts were prepared from bone powder
102 taken from the two ribs. These ranged from 80 to 152 mg. The cervical vertebra (atlas) was
103 treated differently to avoid any destruction of the sample and lesion. It was immersed in 5ml of
104 6M GUSCN extraction buffer in a 50ml conical tube and gently vortex-mixed several times over the
105 course of 1hr. It was then left for one week at 37°C to prevent buffer precipitation. Buffer was
106 recovered by gentle centrifugation (2000 x rpm for 10 mins) and taken forward for DNA recovery
107 using a silica slurry (see below). The atlas sample was washed in an ascending alcohol series (50,
108 70 and 100% ethanol) to remove residual GUSCN traces and then air-dried. It was eventually
109 returned to the other elements of the burial.

110

111 **2.3 DNA extraction.**

112 The bone samples were taken through a GUSCN/silica DNA extraction procedure [7], a
113 modification of the original Boom method [8]. DNA was eluted from the silica in either 65µl (ribs)
114 or 30µl (atlas) of HPLC grade water.

115

116 **2.4. PCR methods.**

117

118 **2.4.1. Mycobacterium tuberculosis (MTB) complex species.**

119 A PCR for the IS6110 insertion element was performed as previously described [9]. This is a
120 modification of the method originally reported by Thierry and colleagues (1990) [10]. The element
121 can be present from low to high copy number in isolates of *M.tuberculosis*. Copy number and
122 preferential insertion site of IS6110 are linked to tuberculosis lineages, reflecting ancestral
123 phylogeography [11]. Whilst some isolates from Southeast Asia can lack IS6110 [12] these are

124 extremely unlikely to be encountered in European strains. Extracts were also tested with a second
125 PCR for the IS element *IS1081*, which is present in 6 copies in members of the MTB complex. A
126 variety of *IS1081* primer combinations were used to assess template size preservation in the
127 extracts [13,14]. A dual-labeled hybridization probe [(HEX) 5'-ATT GGA CCG CTC ATC GCT GCG TTC
128 GC-3' (BHQ-1)] was used to report formation of any product.

129

130 **2.4.2. Differentiation of *M.tuberculosis* complex species.**

131 A polymerase chain reaction (PCR) for *mtp40* was performed using primers which amplify a 113-bp
132 fragment from the *mpcA* gene (Rv2351c). The sequences of these were: F 5'-
133 GGTCTGGTCGAATTCGGTGGAGT-3 and R 5'-ATTCGCGCCCGTTTCGGCGT-3'. The *mtp40* element can
134 be used to identify differences within the *M. tuberculosis* complex. It is present in the vast
135 majority of *M. tuberculosis* isolates and absent from *M. bovis* isolates. It was originally thought
136 that some strains of *M.bovis* retained *mtp40* [15,16] but these have since been shown to be
137 strains of *M.africanum* [17], which are endemic in West Africa and unlikely to have been present
138 in mediaeval Somerset. Absence of *mtp40* from *M. bovis* strains is associated with RD5, an early
139 deletion event in the evolution of the MTB complex. RD5 is 8,964 nucleotides in size and located
140 between genome positions 2,626,067–2,635,031 on the H37Rv reference strain [18].

141

142 **2.4.3. Genotyping using the polymorphic pks15/1 locus of *M.tuberculosis* complex.**

143 We amplified the pks15/1 polymorphic locus to determine whether a characteristic 7-bp deletion
144 event had occurred in the Sk2077 isolate [19]. The forward and reverse primers used were: F 5'-
145 GCCATAAGTCGACCCGCTGC-3' and 5'-GCAGAGGCGCCGGTTGAGGC-3'. These generate a 118-bp
146 amplicon from strains belonging to lineage 4 (L4 or Euro-American) and 125-bp from other
147 *M.tuberculosis* lineages. Amplicon formation was monitored using a specific dual-labelled
148 hydrolysis probe (5'[HEX]AAAGCACCGGGGCGCGCCGTCGAT[BHQ1]-3'). The products were
149 run out on 3% agarose gel to check size and excised bands were purified using a GeneClean
150 DNA isolation kit (Cat. No.1001– 200, MP Biomedicals, California, USA). These were Sanger
151 sequenced at Genewiz Ltd., Takely, Essex, UK.

152

153 **2.4.4. Screening for brucella species DNA.**

154 Brucellosis is often a differential diagnosis in skeletal tuberculosis involving the spine and weight-
155 bearing joints [20]. Therefore the extract prepared from the rib with a lytic lesion was tested for

156 brucella pathogen DNA by PCR with primers which amplify an 85-bp fragment from the IS711
157 repetitive element. This is conserved in multiple copies across the brucella species and biovars.
158 Product was reported using a specific FAM/BHQ1 dual-labelled hybridization probe (Table S3,
159 Supporting information in Bendrey et al, 2020) [21].

160

161 **2.5. Sex determination by amelogenin PCR.**

162 A sex-determining PCR based on polymorphisms in the amelogenin gene was also applied. In this
163 method, males are identified by two PCR bands, one of 105-bp from the Y chromosome and
164 another of 290-bp from the X chromosome. Females generate only the 290-bp product. The
165 sequences of the primers used in this method were (F2) 5'-TGACCAGCTTGGTTCTAWCCC- 3' and
166 reverse (R1) 5'-CARATGAGRAAACCCAGGGTTCCA-3' [22].

167

168 **2.6. PCR reaction conditions.**

169 PCR for all methods was performed in a final volume of 15 µl, using the HotStart Taq Master Mix
170 Kit from Qiagen (product 203445). The reactions contained 25 pmol of forward and reverse
171 primers, each in 1 µl, 7.5 µl of kit master mix, 1.5-µl non-acetylated bovine serum albumin (BSA,
172 10 mg ml⁻¹, Sigma B4287) and 3 µl of the template. The intercalating dye EVAGreen® (Biotium,
173 code BT31000) was used to report product formation in non probe-based PCR reactions. The kit
174 magnesium ion concentration of 1.5mM per reaction was supplemented to 2mM for PCR methods
175 using EVAGreen® dye and to 3mM MgCl₂ for real-time PCR when using any of the labeled
176 hybridization probes. All probes were used at a final concentration of 100 nM. The volumes were
177 made up to 15 µl with molecular biology grade water (Sigma-Aldrich). After an initial activation
178 step of 14 min at 95^o C, 41-45 cycles of amplification were performed on an Mx3005P RT-PCR
179 platform (Agilent Technologies). When using the GC-rich pks15/1 probe, an extra 4th PCR step of
180 10s was included to acquire fluorescence data at 85C. Non-template controls contained water in
181 place of DNA extract.

182

183 **2.7. Gel electrophoresis.**

184 PCR products were run out on 3% agarose gels in a TAE buffer system alongside DNA size markers
185 (100-bp DNA ladder, Promega) to confirm amplicon size.

186

187 **2.8. Measures to prevent contamination.**

188 Separate laboratories were used for each of the three main stages of the aDNA analyses, these
189 being extraction, amplification and post-PCR steps such as gel electrophoresis. The pre- and post-
190 PCR laboratories were physically separated and independently equipped with pipettes, fridge
191 freezers, mixers and bench top centrifuges, disposable plastic ware, filter pipette tips and other
192 reagents dedicated to the project. Surfaces and equipment in the clean 'set-up' laboratory in
193 contact with sample tubes (centrifuges, rotors, mixers, etc.) were cleaned before each assay.
194 Template blanks were run alongside bone extracts in the PCR machine to screen for random
195 contamination. Except for one amelogenin PCR, positive controls were not included in any of the
196 experiments.
197

198 **3. RESULTS.**

199 **3.1. Estimation of age.**

200 Based upon formation and eruption of the dentition, age of individual Sk2077 was estimated to be
201 3-5 years of age at the time of death.

202

203 **3.2. MTB complex screening.**

204 a). Both rib extracts and the atlas were all found to be positive for IS6110 PCR. This IS element can
205 be present in up to 30+ copies in the *M. tuberculosis* genome, depending on strain lineage and is
206 one of the most sensitive markers of complex members. [Figure 2](#) shows IS6110 amplification and
207 dissociation profiles (melt analysis) in the extracts from one of the rib samples and from the atlas.

208

209 The extract prepared from the atlas displayed a shallower amplification profile, reaching a lower
210 final fluorescence value compared to the rib extract. This was also reflected in the melt analysis
211 curve. This might suggest that inhibitors of the PCR reaction could have been co-extracted along
212 with remnant aDNA templates. A number of substances present in the environment are known to
213 cause PCR inhibition, particularly humic and fulvic acids [[23](#), [24](#)] and can quench fluorescence
214 values. In most instances, the amplification buffer system we use, which includes a final
215 concentration of 1mg/ml non-acetylated BSA, overcomes such problems.

216

217 b). Screening for the IS element IS1081 was successful when applied to the extract prepared from
218 the atlas ([Figure 3](#)). However, we found that successful product amplification size was restricted to
219 primers which generated an amplicon of 79-bp and was not positive when trying to amplify either
220 135-bp templates or the intermediate size of 113-bp, suggesting particularly fragmented DNA
221 ([Table 1](#)).

222

223 **3.3. Species testing with *mtp40* PCR.**

224 The extract prepared from the atlas was tested for the *mtp40* element and was found to be
225 positive ([Figure 4](#)). Repeat testing for IS6110 was performed at the same time and this test was
226 again seen to be positive, generating the expected 123-bp product.

227

228 **3.4. Genotyping using the polymorphic pks15/1 locus.**

229 The real-time PCR probe for the pks15/1 locus reported product formation in duplicate samples of
230 the atlas extract (Figure 5a). Subsequent gel electrophoresis showed band sizes of about 120-bp.
231 When sequenced, the amplicon clearly showed that it was identical to lineage 4 isolates of the
232 *M.tuberculosis* complex in which a 7-bp deletion event has occurred (Figure 5b).

233

234 **3.5. Screening for brucella species DNA.**

235 There was no indication of brucella pathogen DNA in either of the ribs or cervical vertebra.

236

237 **3.6. Sex determination by amelogenin PCR.**

238 One of the two rib extracts generated a single peak on real-time PCR which melted at 79.7⁰C, the
239 same temperature as the Y chromosome product in the melt curve analysis (Figure 6, panel a).

240 Furthermore, when run out on a 3% agarose gel the product was seen to be a single band of
241 expected size (Ca. 105-bp), matching the male reference sample smaller band (Figure 6, panel b).

242 The second expected X chromosome product of 290-bp was not amplified from Sk2077, consistent
243 with heavily fragmented template DNA in this individual.

244

245 4. DISCUSSION.

246

247 A re-examination of the remains of Sk2077 has confirmed a diagnosis of infection with a member
248 of the MTB complex. This is indicated by the positive PCR findings for both IS6110 and IS1081. The
249 fact that Sk2077 was additionally positive for the *mtp40* element indicates that the species
250 involved was a strain of *M.tuberculosis sensu stricto*, rather than *M.bovis* as the latter have lost
251 this locus as part of the RD5 deletion event [18]. Further genotyping with the polymorphic pks15/1
252 locus showed that a 7-bp deletion, characteristic of lineage 4 had occurred. Strains of
253 *M.tuberculosis* with this deletion are deficient in the production of phenolphthiocerol derivatives
254 [19]. The isolate in Sk2077 therefore belongs to this ancestry, sometimes referred to as the Euro-
255 American lineage [25]. This is one of the more globally widespread of the *M.tuberculosis* lineages.

256

257 All the biomolecular findings indicated that DNA remaining in the burial was heavily fragmented.
258 For this reason and to avoid further destruction of precious material, Individual Sk2077 was not
259 considered to be a suitable candidate for wider genome characterisation by next generation
260 sequencing (NGS). A non-destructive means of DNA extraction was tried here for the atlas bone
261 and this allowed a fairly easy means of preserving an important specimen without loss of the
262 physical lesions. The GUSCN buffer and vortex mixing dislodged some looser bone particles but
263 otherwise the sample showed no evidence of having been processed and was eventually returned
264 to the burial.

265

266 Although unlikely, our study does not completely rule out that the individual may have suffered
267 from concomitant Langerhans cell histiocytosis (LCH). The etiology of LCH is still poorly understood
268 but there is growing evidence to suggest that it represents a rare cancer and is associated with
269 specific gene mutations. The most frequent genetic association is with the oncogenic V600E BRAF
270 mutation, which has been reported to occur in approximately 60% of LCH cases [26]. Assay of
271 aDNA for such markers of LCH, and indeed other non-communicable diseases, is possible but due
272 to the limited and degraded DNA, we restricted our “host” analysis in this study to sex
273 determination.

274

275 Thus, as well as demonstrating the presence of tuberculosis pathogen DNA, we were able to show
276 that the remains were those of a young male child. In adults the overall tuberculosis sex ratio

277 (male: female) is often quoted at around 2:1 [27,28]. However, the male: female ratio of
278 tuberculosis infection for younger children like Sk2077 is nearer 1:1. This ratio increases with age,
279 with males having a higher ratio than females from the 2nd decade onwards, peaking in the 6th
280 decade (to 3.4:1) then decreasing until the eighth decade, when it rises again [28]. However,
281 information for the male: female ratio of tuberculosis in the medieval period is lacking.

282

283 In children of this age (3-5 years), infection is often the result of exposure to an infected adult,
284 usually a parent or other household member with contagious pulmonary tuberculosis. The
285 positivity of Sk2077 infers that it is very likely that tuberculosis was present amongst the adult
286 population that this cemetery served, even though it may not be apparent on the skeletal
287 remains. This is unsurprising, as only a small percentage of tuberculosis cases result in
288 characteristic skeletal patterning [29].

289

290 Young children once exposed, also have a higher risk of progression to disease and are more likely
291 to develop severe or disseminated TB. It is thought that up to 50% of children exposed to
292 tuberculosis may go on to develop symptoms of the disease within 6-9 months. In comparison, the
293 rates in immuno-competent adults exposed to tuberculosis may be only 5-10% over the course of
294 their whole lifetime [30].

295

296 The bone lesions indicative of tuberculosis in Sk2077 point to a chronic infectious process of at
297 least several months duration or possibly longer [31]. The rib lesions and other widespread signs
298 of tuberculosis suggest this probably started in the lungs and spread to the ribs, lymph nodes [32]
299 and other soft tissues, followed by other parts of the skeleton including the cranium, possibly
300 ultimately resulting in tuberculous meningitis. Calvarial involvement is generally a very rare
301 manifestation of extrapulmonary tuberculosis. The spread to the right parietal bone in Sk2077
302 may have been via the haematogenous route with seeding to the spongy cancellous diploë
303 separating the inner and outer layers of skull cortical bone [33].

304

305 Since Dawson and Robson Brown (2012) [1] published their initial findings on Sk2077, research
306 into the palaeopathology of children has continued to flourish with new comparison studies
307 illustrating the presence of the types of lesions present on Sk2077 and their association with TB as
308 cause of death.

309 Clinical cases of cranial lesions in association with TB in living individuals have been reported by

310 Datta *et al.* 2017 [34], including a young adult male exhibiting a 4-mm defect in the outer table of
311 the calvaria near the parieto-occipital suture and an adolescent girl with lytic destruction of the
312 left frontal and squamous part of the temporal bone. Archaeological examples with lesions similar
313 to those on Sk2077 are presented in Table 2.

314

315 Lytic cranial lesions have been reported by Columbo *et al.* (2015) [35] on a mediaeval child (1-2.5
316 years) from France, and they also suggested a diagnosis of either Langerhans cell histiocytosis or
317 TB, or in fact perhaps both conditions, as well as by Abegg *et al.* (2020) [36] on a Neolithic child (2-
318 6 years) from Switzerland, and Geber (2015) [37] on a post medieval child (9 years) from Ireland.
319 Examples of endocranial lesions (SES) in association with periosteal new bone formation (PNB) on
320 the long bones have been reported by Hershkovitz *et al.* (2015) [38], Abegg *et al.* (2020) [36] and
321 Collins (2020) [39]. Hershkovitz *et al.* (2015) [38] detected *M. tuberculosis* aDNA from an infant
322 Neolithic skeleton from Atlit-Yam in the Eastern Mediterranean. The infant had both endocranial
323 lesions (SES) and periosteal lesions on the long bones, whilst a young adult female in the same
324 grave presented periosteal lesions on one tibia bone also tested positive.

325 Lytic lesions on the ribs of a 9-10 year old child from a Christian cemetery site, Roman Pécs,
326 Hungary, show a similar scooped out appearance to those of Sk2077 and were reported in
327 association with more classic lesions of the vertebrae causing collapse and kyphosis [40];
328 periosteal new bone formation was also noted on the femur and tibia. Molecular analysis was
329 undertaken in this case but the sequencing failed to provide sufficient data for a diagnosis.

330

331 The presence of lesions on the cervical vertebrae, as seen in Sk2077, appears to be rare in the
332 literature, something noted by Lewis in 2018 [41]. Spekker *et al.* [42] present a case of TB from a
333 12 year old child with pitting and slight cortical remodelling on the first to fifth cervical vertebrae
334 with more marked destructive lesions on the rest of the spine. Pitting was also noted on the
335 proximal ends of the ribs. A case of a five year old child from Neolithic Italy has clustered pitting
336 and cavitation on the inferior surface of the body of the fourth cervical vertebra alongside
337 evidence for lytic lesions on the ribs and some PNB on the long bones (Sparacello *et al.* 2017) [43].
338 Cases described by Walker (2012) [44] and Collins (2020) [39] show lytic activity affecting the
339 laminae of the atlas and/or cervical vertebrae (as was seen in the atlas and axis of Sk2077) a
340 diagnosis of possible TB was given in these cases. One case of a 17 year-old male from the Terry
341 Anatomical collection, USA and known to have died from TB in the twentieth century, shows
342 destructive lesions of the atlas [45], although in this case most of the vertebral column was also

343 affected by destructive lesions.

344

345 Relatively little is known of TB lineages present in archaeological material from Britain. The earliest
346 confirmed case of tuberculosis in Britain dates to the late Iron Age and comes from Tarrant Hinton
347 in Dorset [46]. It involved a male individual of about 40 years of age at death showing signs of
348 Pott's disease. Genotyping showed this was due to a strain of *M.tuberculosis* rather than *M.bovis*.
349 In addition, the strain was shown to have undergone the TbD1 deletion, indicating the isolate
350 would belong to one of three possible lineages of "modern" *M.tuberculosis*, these being lineages
351 two, three or four [25].

352

353 In a wide-ranging study of British and European cases of probable TB Müller et al, (2014) [47]
354 confirmed the pathogen DNA in a total of eight cases from Britain using PCRs for both IS6110 and
355 IS1081 insertion elements, with confirmation by either probe or sequencing of the cloned
356 amplicons. The dates of these cases ranged from 11th to mid 19th centuries. They confirmed that
357 ribs with visceral lesions were generally good samples to select to study for evidence of MTB
358 complex DNA. However, there was no attempt to identify the species involved or to which
359 lineages the strains belonged.

360

361 A study of burials from the deserted mediaeval village of Wharram Percy (WP) verified ancient TB
362 DNA in a total of nine cases. Six were male and three female, with ages ranging from 25-50 plus
363 years. The dates of these individuals spanned from early 10th right up to late 16th century [48]. A
364 variety of genotyping PCRs were applied and all cases were again found to be due to
365 *M.tuberculosis sensu stricto* based on either a characteristic mutation in the *oxyR* pseudogene, or
366 the presence of species-specific spacer patterns in the spoligotyping procedure [49].

367

368 A further three cases of tuberculosis including burials G658, EE002, and EE005 (all juveniles, with
369 age estimated around 10-11 years) from WP were later identified through the study of individuals
370 either with or without periostitic rib lesions, seen as a proxy marker for pulmonary tuberculosis
371 [50]. One further individual from WP, EE062, a male aged 30-40 years with hypertrophic
372 pulmonary osteopathy (HPO) was also found to be positive for a strain of *M.tuberculosis* [51],
373 suggesting HPO was induced by tuberculosis infection in this case.

374

375 Finally, Bouwman and colleagues [52] used hybridization sequence capture followed by next

376 generation sequencing (NGS) to successfully analyse a strain of *M.tuberculosis* recovered from a
377 19th century female burial (Sk4006, 16-18 years) from St. George's crypt, Leeds, West Yorkshire.
378 Additionally, a number of loci were independently amplified by PCR and sequenced to confirm the
379 capture array data. The strain found by these workers can also be described as "modern", having
380 lost the TbD1 deletion. It had also undergone the 7-bp deletion in the *pks15/1* locus, indicating it
381 too belonged to the Euro-American clade (lineage 4). This remains one of the most fully typed
382 historic isolates of *M.tuberculosis* from Britain, although late in the sequence of known cases.
383

384 **5. CONCLUSIONS.**

385 Biomolecular analysis extracts prepared from skeletal elements of a young child from late
386 mediaeval Taunton, Somerset, England confirmed a diagnosis of infection with a strain of
387 *M.tuberculosis* belonging to lineage 4. These findings point to the presence of tuberculosis in
388 adult members of the same mediaeval community. Sex determination using amelogenin PCR was
389 able to show these were the remains of a young male child.

390

391 **ACKNOWLEDGEMENTS.**

392 We thank Professor Katherine Robson Brown, Director of the Jean Golding Institute, University of
393 Bristol, UK for providing access to material from the Taunton cemetery site and Mr. Richard
394 McConnell and Dr. Cheryl Green of Context One Archaeological Services, Dorset, UK for access to
395 the images from the excavation archive. Last, but not least, we are grateful to the two anonymous
396 referees for the time spent in reviewing our manuscript and their constructive comments.
397

398 **FUNDING.**

399 This research did not receive any specific grant from funding agencies in the public, commercial, or
400 not-for-profit sectors.

623 lesion (blue traces) and the cervical vertebra (pink traces). Panel b): Dissociation analyses from the
624 same experiment with specific product showing a melt temperature of around 90.5C. Experiments
625 were run on an MxPro 3005P real-time platform (Agilent Technologies).

626

627 Figure 3. IS1081 real-time PCR amplification profiles for Sk2077 atlas (red traces) and for two
628 template blanks (black traces). IS1081 product amplified using primer pair F3/R3 was reported
629 with a HEX labelled specific hybridization probe. These are the results of experiment 2 mentioned
630 in Table 1.

631

632 Figure 4. Gel electrophoretic separation of IS6110 and *mtp40* PCR products from Sk2077 run on
633 3% agarose. Lanes 1 and 2 = IS6110 PCR product (123-bp). Lanes 3 and 4 = template blanks. Lane L
634 = 100-bp DNA size markers. Bright band (arrowed) represents 500-bp size marker. Lanes 5 and 6:
635 *mtp40* PCR product (113-bp). Lanes 7 and 8: Template blanks for the *mtp40* PCR experiment.

636

637 Figure 5. Upper panel a): Real-time PCR amplification profile of the pks15/1 locus from Sk2077
638 (blue traces) and a water blank (black trace) with product monitored with a specific dual-labelled
639 hydrolysis probe. Lower panel b) shows sequencing of the purified PCR product with position of
640 the 7-bp deletion (GGGCCGC) [19] highlighted in yellow.

641

642 Figure 6, panel a). Dissociation (melt) curve analyses of amelogenin PCR showing profiles of male
643 subject DNA (blue trace, two peaks), female subject DNA (red trace, one peak) and rib extract
644 from Sk2077 (green trace, one peak). A template or water blank negative control is included (black
645 trace, flatline). Note same Tmelt of Sk2077 as the smaller male peak from reference male DNA at
646 79.7C.

647

648 Figure 6, panel b). Extended gel electrophoretic separation of products from the same experiment
649 shown in panel a). Lane 1 = template blank. Lane 2 = Sk2077 rib product. Lanes 3 and 4, nil.
650 Lanes 5 and 6 contain male and female reference DNA respectively. Lane 7 shows 100-bp DNA size
651 markers for comparison. Position of arrow indicates position of expected 105-bp Y chromosome
652 product generated from Sk2077.
